Abstract: Generally the Power circuit topology of the single phase PV system will be a good choice for low-rated photo voltaic inverters of rating less than a kilowatt. In the ideal case the system will not have any lower order harmonics. However, some dominant factors result in lower order harmonics in the system such as on-state voltage drops across the switches and the distortion in the grid voltage itself etc. This dc injection into the primary of the transformer will result in even harmonics which are being drawn from the grid, again providing a lower power quality.

In this work, a single-phase grid-connected photovoltaic inverter topology consists of a boost section, a low-voltage single-phase H-bridge inverter with an inductive filter, and a step-up transformer interfacing the grid is presented. A novel design of inverter current control that attenuates the lower order harmonics is presented in this project. An adaptive harmonic compensation technique with its design is proposed for the lower order harmonic compensation. In addition, a proportional-resonant-integral (PRI) controller and its design is also proposed.

So, in this project some modification is made in the inverter current control for a grid connected single-phase photovoltaic inverter for ensuring high quality of the current to be injected into the grid.

Keywords: Adaptive filters, Harmonic distortion, Inverters, Solar energy.

I. INTRODUCTION

Now a days energy demand has been increasing day to day as the standard of living of people of any country is proportional to the energy consumption made by them. We know that basically there are two types of energy sources namely conventional energy sources and renewable energy sources.

Renewable energy sources like solar, wind, and geothermal became popular due to the depletion of conventional energy sources. Hence, many distributed generation (DG) systems making use of the renewable energy sources are being designed and connected to a grid. In this work, one such Distributed Generation system with solar energy as the source is considered. The solar inverter system topology consists of the following three power circuit stages as shown in figure1.

![Power circuit topology of the 1-φ PV system for a low-voltage inverter](image)

Fig1: Power circuit topology of the 1-φ PV system for a low-voltage inverter

The switches in Fig. 1 are rated for the low voltage which results in reduction of cost, the component count will be reduced and the overall reliability of the system increases. The above circuit comprises of a low voltage inverter with 40v dc bus connected to 230v grid using step up transformer. This topology consists of a PV array which is a combination of eight PV panels; each panel consists of three modules and it is a good choice for low-rated PV inverters of rating less than a kilowatt. When compared to the other systems this topology has a relatively larger size of the interface transformer which is a disadvantage. Other topologies consist of a high-frequency link transformer.

There can be a dc injection into the transformer primary due to a number of reasons. They are varying power reference from a fast MPPT block from which the ac current reference is generated which is given as reference for error detection, the offsets in the sensors, and A/D conversion block in the digital controller. This dc injection would result in even harmonics being drawn from the grid.

It is important to attenuate these lower order harmonics in order for the PV inverter to meet standards such as IEEE 519-1992 and IEEE 1547-2003. Hence, In this work we concentrate on the design of the inverter current control in order to achieve a good attenuation of the lower order harmonics. It must be observed that attenuating the lower order harmonics using a larger output filter inductance is not good because it increases losses in the system along with a larger fundamental voltage drop and cost will be increased.
This work includes an analysis to design the value of the gain in the proportional resonant controller to achieve an adequate level of harmonic compensation. With the help of this scheme overall system dynamics is also analyzed. Adaptive filter method is simple for implementation and hence it can be implemented in a low-end digital controller.

The presence of dc in the inverter terminal voltage results in a dc current flow into the primary of the transformer. This dc current results in drawing even harmonics from the grid. If the main controller used is a Proportional Resonant controller, any dc offset in a control loop will propagate through the system and the inverter terminal voltage will have a nonzero average value. Thus, in this work, a modification to the conventional PR controller scheme is proposed. An integral block is used along with the PR controller to ensure that there is no dc in the output current of the inverter. This would automatically eliminate the even harmonics. This scheme is termed as proportional-resonant-integral (PRI) control and the design of the PRI controller parameters is provided in this work.

II. ORIGIN OF LOWER ORDER HARMONICS

A. Odd Harmonics

The dominant causes for the lower order odd harmonics are the distorted magnetizing current drawn by the transformer, the inverter dead time, and the semiconductor device voltage drops. Other factors are the distortion in the grid voltage itself and the voltage ripple in the dc bus. The magnetizing current drawn by the transformer contains lower order harmonics due to the nonlinear characteristics of the B–H curve of the core. The exact amplitude of the harmonics drawn can be obtained theoretically if the B–H curve of the transformer is known. The phase angle of the harmonics due to the magnetizing current will depend on the power factor of operation of the system. As the operation will be at unity power factor (UPF), the current injected to the grid will be in phase with the grid voltage. However, the grid voltage leads the magnetizing current by 90°. Hence, the harmonic currents will have a phase displacement of either +90° or −90° depending on harmonic order.

The dead-time effect introduces lower order harmonics which are proportional to the dead time, switching frequency, and the dc bus voltage. The dead-time effect for each leg of the inverter can be modeled as a square wave error voltage out of phase with the current at the pole of the leg. The device drops also will cause a similar effect but the resulting amount of distortion is smaller compared to that due to the dead time. Thus, for a single-phase inverter topology considered, net error voltage is the voltage between the poles and is out of phase with the primary current of the transformer.

Using the values of the filter inductance, transformer leakage inductance, and the net series resistance, the harmonic current magnitudes can be evaluated. Again, it must be noted that the phase angle of the harmonic currents in this case will be 180° for UPF operation. Thus, it can be observed that the net harmonic content will have some phase angle with respect to the fundamental current depending on the relative magnitudes of the distortions due to the magnetizing current and the dead time.

B. Even Harmonics

The topology under consideration is very sensitive to the presence of dc offset in the inverter terminal voltage. The dc offset can enter from a number of factors such as varying power reference given by a fast MPPT block, the offsets in the A/D converter, and the sensors. To understand how a fast MPPT introduces a dc offset, consider Figs. 2 and 3. In Fig. 2, \( \hat{d}_{\text{boost}} \) is the duty ratio command given to the boost converter switch, \( V_{PV} \) and \( I_{PV} \) are the panel voltage and current, respectively. \( P_{PV} \) is the panel output power, \( V_g \) is the rms value of the grid voltage, \( \sin \theta \) is the in-phase unit vector for the grid voltage, and \( i^* \) is the reference to the current control loop from an MPPT block. As the power reference keeps on changing due to fast MPPT action, the current reference may have a nonzero average value, which is illustrated in Fig. 3 for a step change in power reference which repeats.

III. PROPOSED TOPOLOGIES

A. Introduction to the PRI Controller:

Conventional stationary reference frame control consists of a PR controller to generate the inverter voltage reference. In this work, a modification to the PR controller is proposed, by adding an integral
block, GI as indicated in Fig.4. The modified control structure is termed as a PRI controller. Proportional integral controller is most widely used controller but it consists of a zero at the fundamental frequency so, it is not possible to eliminate the steady state error completely. In case of proportional resonant controller, at resonant frequency the gain will be increased and it makes the system effective.

The inverter will have a gain of to the voltage reference generated by the controller and the impedance offered is given by (Rs + SLs) in s-domain. Rs and Ls are the net resistance and inductance referred to the primary side of the transformer, respectively. Ls includes the filter inductance and the leakage inductance of the transformer. Rs is the net series resistance due to the filter inductor and the transformer. The PRI controller is proposed to ensure that the output current of the system does not contain any dc offset.

The PRI controller introduces a zero at s = 0 in the closed-loop transfer function. Hence, the output current will not contain any steady state dc offset. This is necessary in the topology considered because the presence of a dc offset would result in a flow of even harmonics. The following section explains the design of PR controller parameters and proposes a systematic method of selecting and tuning the gain of the integral block in the PRI controller.

B. complete current control structure:

The overall current control block diagram with the adaptive compensation is shown in Fig.5. Note that the fundamental current control is done using the transformer primary current and the harmonic compensation block uses the secondary current, which is the current injected into the grid. Fig.5 shows only one adaptive harmonic compensation block for the kth harmonic. If say dominant harmonics third, fifth, and seventh need to be attenuated, then three adaptive filters and three gain terms kadapt are required and the net voltage reference added to the output of the PRI controller will be the sum of the voltage references generated by each of the block.

Thus, depending on the number of harmonics to be attenuated, the number of blocks can be selected. Note that n in Fig.5 is the transformer turns ratio from secondary to primary. i_{sec,k,t} is the net kth harmonic current in the secondary, which is estimated using the LMS adaptive filter. This is mainly due to the harmonics in the magnetizing current and the dead-time effect. A single-phase PLL is used to generate the reference sine–cosine signals synchronized with the grid voltage for the adaptive filter. Next, computation of the adaptive gain kadapt is discussed.

Based on the estimated net kth harmonic in the grid current, the voltage reference V_{k,ref} is generated by multiplying the estimated harmonic with kadapt. The effect of this voltage reference is that it results in an amplified voltage at that harmonic frequency at the
inverter terminals and this will inject a current at that frequency in the primary side. The reflected secondary current will oppose the original current that was present in the secondary and hence there will be a net reduction in that particular harmonic in the grid current. The amount of reduction of the harmonic in grid current will depend on $k_{\text{adapt}}$.

CONCLUSION

Modification to the inverter current control for a grid connected single-phase photovoltaic inverter has been proposed in this work, for ensuring high quality of the current injected into the grid. The proposed method uses an LMS adaptive filter to estimate a particular harmonic in the grid current that needs to be attenuated. The design of the gain of a proportional controller to have an adequate harmonic compensation has been explained. To avoid dc biasing of the transformer, a novel Proportional Resonant Integral controller has been proposed and its design has been presented. The PRI controller and the adaptive compensation scheme together improve the quality of the current injected into the grid.
